

Ceratostigma - Growing Guide

Ceratostigma - Growing Guide

Shrubby plumbago

Ceratostigma are always popular shrubs because they have the great merit of having blue flowers. The generic name refers to the horn-like outgrowths on the stigma. These are useful evergreen and deciduous shrubs, originally from China and the Himalayas, with five lobed blue flowers borne in spike-like clusters from late summer to autumn. They can be grown in sun and shelter; perhaps against a warm wall in a shrub or a mixed border. The varieties which we grow are perfectly hardy although shrubby species may experience some dieback after a cold winter. The shrubby species can therefore benefit from a light top pruning in spring to remove any deadwood, to keep them in shape, and encourage better flowering in the following season. *C. plumbaginoides* is also suitable as groundcover or in the rock garden and requires no pruning.

C. abyssinicum is the exception to the above in that, despite being a sturdy growing shrub with sky-blue flowers, it is only half hardy and is therefore probably only for the greenhouse or patio.

*Ceratostigma
abyssinicum*

C. griffithii is a rounded evergreen shrub or sub-shrub which grows to around 3ft in height with a larger spread. The large flowers are bright blue in spike-like terminal clusters and the leaves turn red in autumn and winter.
