

Zelkova - Growing Guide

Growing Zelkova

Zelkova are hardy ornamental parkland trees which have equal standing in this sphere to the similarly deciduous species of *Nothofagus* (southern beech). Zelkova are however related to *Ulmus* (elms) and are commonly mistaken as these because of the similarity of their leaves which are also coarse to the touch. They differ from elms in having rounded rather than winged fruits and in their simple (rather than double) toothed leaves. Zelkova flowers are small and greenish and of no great significance although both male and bisexual flowers appear on the same tree.

Z. serrata originates from Korea, Japan and Taiwan. It has a broad spreading habit and, at Caerhays, we have made the error of not giving it enough space to spread and develop in its chosen planting spot. *Z. serrata* can grow up to 100ft tall with a spread at least half this in maturity. The tree has smooth grey bark and 5in long dark green leaves with up to 16 teeth on each side. Autumn colours range from yellow to orange or red and, while not perhaps the most spectacular, they are certainly well worth their place.

Zelkova seeds can be sown in pots outdoors in the autumn. Softwood cuttings are only likely to succeed if taken from young plants.
